

Regular Expressions

Data Wrangling, Session 5

Kieran Healy

Code Horizons

July 19, 2024

A brief introduction to regular expressions

Load the packages, as always

```
library(here)      # manage file paths  
library(socviz)    # data and some useful functions
```

```
library(tidyverse) # your friend and mine  
library(gapminder) # gapminder data  
library(stringr)
```

Regular Expressions

Or, waiter, there appears to be a language inside my language

stringr is your gateway to regexps

```
library(stringr) # It's loaded by default with library(tidyverse)
```

regexps are their own whole world

This book is a thing of beauty.

Searching for patterns

A regular expression is a way of searching for a piece of text, or *pattern*, inside some larger body of text, called a *string*.

The simplest sort of search is like the “Find” functionality in a Word Processor. The pattern is a literal letter, number, punctuation mark, word or series of words; the text is a document searched one line at a time. The next step up is “Find and Replace”.

Every pattern-searching function in `stringr` has the same basic form:

```
str_view(<STRING>, <PATTERN>, [ ... ]) # where [ ... ] means "maybe some options"
```

Functions that *replace* as well as *detect* strings all have this form:

```
str_replace(<STRING>, <PATTERN>, <REPLACEMENT>)
```

(If you think about it, `<STRING>`, `<PATTERN>` and `<REPLACEMENT>` above are all kinds of pattern: they are meant to “stand for” all kinds of text, not be taken literally.)

Searching for patterns

Here I'll follow the exposition in Wickham & Grolemund (2017).

```
x ← c("apple", "banana", "pear")  
str_view(x, "an", html=FALSE)
```

```
[2] | b<an><an>a
```

Searching for patterns

Regular expressions get their real power from *wildcards*, i.e. tokens that match more than just literal strings, but also more general and more complex patterns.

The most general pattern-matching token is, “Match everything!” This is represented by the period, or `.`

But ... if `.` matches any character, how do you specifically match the literal character `.`?

Escaping

You have to “escape” the period to tell the regex you want to match it exactly, rather than interpret it as meaning “match anything”.

regexs use the backslash, `\`, to signal “escape the next character”.

To match a `.`, you need the regex `\.`

Hang on, I see a further problem

We use strings to represent regular expressions. `\` is also used as an escape symbol in strings. So to create the regular expression `\.` we need the string `\\.`

```
# To create the regular expression, we need \\  
dot ← "\\."  
  
# But the expression itself only contains one:  
writeLines(dot)
```

```
\\.
```

```
# And this tells R to look for an explicit .  
str_view(c("abc", "a.c", "bef"), "a\\.c")
```

```
[2] | <a.c>
```

But ... how do you match a **literal** \?

```
x ← "a\\b"  
writeLines(x)
```

```
a\b
```

```
#> a\b
```

```
str_view(x, "\\") # you need four!
```

```
[1] | a<\>b
```

But ... how do you match a **literal** \?

This is the price we pay for having to express searches for patterns using a language containing these same characters, which we may also want to search for.

**I *promise* this will
pay off**

Matching start and end

Use **^** to match the start of a string.

```
x ← c("apple", "banana", "pear")  
str_view(x, "^a")
```

```
[1] | <a>pple
```

Matching start and end

Use **^** to match the start of a string.

```
x ← c("apple", "banana", "pear")  
str_view(x, "^a")
```

```
[1] | <a>pple
```

Use **\$** to match the end of a string.

```
str_view(x, "a$")
```

```
[2] | banan<a>
```

Matching start and end

To force a regular expression to only match a complete string, anchor it with both **^** and **\$**

```
x ← c("apple pie", "apple", "apple cake")  
str_view(x, "apple")
```

```
[1] | <apple> pie  
[2] | <apple>  
[3] | <apple> cake
```

```
str_view(x, "^apple$")
```

```
[2] | <apple>
```

Matching character classes

`\d` matches any digit.

`\s` matches any whitespace (e.g. space, tab, newline).

`abc` matches a, b, or c.

`^abc` matches anything except a, b, or c.

Matching the *special* characters

Look for a literal character that normally has special meaning in a regex:

```
str_view(c("abc", "a.c", "a*c", "a c"), "a[.]c")
```

```
[2] | <a.c>
```

```
str_view(c("abc", "a.c", "a*c", "a c"), ".[*]c")
```

```
[3] | <a*c>
```

This works for most (but not all) regex metacharacters: `$.|?*+()[]{.`

Unfortunately, a few characters have special meaning even inside a character class and must be handled with backslash escapes. These are `]` `\` `^` and `-`

Alternation

Use parentheses to make the precedence of the 'or' operator **|** clear:

```
str_view(c("groy", "grey", "griy", "gray"), "gr(ela)y")
```

```
[2] | <grey>
```

```
[4] | <gray>
```

Repeated patterns

? is 0 or 1

+ is 1 or more

* is 0 or more

```
x ← "1888 is the longest year in Roman numerals: MDCCCLXXXVIII"  
str_view(x, "CC?")
```

```
[1] | 1888 is the longest year in Roman numerals: MD<CC><C>LXXXVIII
```

Repeated patterns

? is 0 or 1

+ is 1 or more

* is 0 or more

```
str_view(x, "CC+")
```

```
[1] | 1888 is the longest year in Roman numerals: MD<CCC>LXXXVIII
```

Repeated patterns

? is 0 or 1

+ is 1 or more

* is 0 or more

```
x ← "1888 is the longest year in Roman numerals: MDCCCLXXXVIII"  
str_view(x, 'C[LX]+')
```

```
[1] | 1888 is the longest year in Roman numerals: MDCC<CLXXX>VIII
```

Exact numbers of repetitions

$\{n\}$ is exactly n

$\{n,\}$ is n or more

$\{,m\}$ is at most m

$\{n,m\}$ is between n and m

```
str_view(x, "C{2}")
```

```
[1] | 1888 is the longest year in Roman numerals: MD<CC>CLXXXVIII
```

Exact numbers of repetitions

`{n}` is exactly n

`{n,}` is n or more

`{,m}` is at most m

`{n,m}` is between n and m

```
str_view(x, "C{2,}")
```

```
[1] | 1888 is the longest year in Roman numerals: MD<CCC>LXXXVIII
```

Exact numbers of repetitions

`{n}` is exactly n

`{n,}` is n or more

`{,m}` is at most m

`{n,m}` is between n and m

```
str_view(x, "C{2,3}")
```

```
[1] | 1888 is the longest year in Roman numerals: MD<CCC>LXXXVIII
```

Exact numbers of repetitions

`{n}` is exactly n

`{n,}` is n or more

`{,m}` is at most m

`{n,m}` is between n and m

By default these are *greedy* matches. You can make them “lazy”, matching the shortest string possible by putting a `?` after them. **This is often very useful!**

```
str_view(x, 'C{2,3}?')
```

```
[1] | 1888 is the longest year in Roman numerals: MD<CC>CLXXXVIII
```

Exact numbers of repetitions

`{n}` is exactly n

`{n,}` is n or more

`{,m}` is at most m

`{n,m}` is between n and m

By default these are *greedy* matches. You can make them “lazy”, matching the shortest string possible by putting a `?` after them. **This is often very useful!**

```
str_view(x, 'C[LX]+?')
```

```
[1] | 1888 is the longest year in Roman numerals: MDCC<CL>XXXVIII
```

And **finally** ... backreferences

fruit # built into stringr

[1] "apple"	"apricot"	"avocado"
[4] "banana"	"bell pepper"	"bilberry"
[7] "blackberry"	"blackcurrant"	"blood orange"
[10] "blueberry"	"boysenberry"	"breadfruit"
[13] "canary melon"	"cantaloupe"	"cherimoya"
[16] "cherry"	"chili pepper"	"clementine"
[19] "cloudberry"	"coconut"	"cranberry"
[22] "cucumber"	"currant"	"damson"
[25] "date"	"dragonfruit"	"durian"
[28] "eggplant"	"elderberry"	"feijoa"
[31] "fig"	"goji berry"	"gooseberry"
[34] "grape"	"grapefruit"	"guava"
[37] "honeydew"	"huckleberry"	"jackfruit"
[40] "jambul"	"jujube"	"kiwi fruit"
[43] "kumquat"	"lemon"	"lime"
[46] "loquat"	"lychee"	"mandarine"
[49] "mango"	"mulberry"	"nectarine"
[52] "nut"	"olive"	"orange"
[55] "pamelo"	"papaya"	"passionfruit"

Grouping and backreferences

Find all fruits that have a repeated pair of letters:

```
str_view(fruit, "(..)\1", match = TRUE)
```

```
[4] | b<anan>a  
[20] | <coco>nut  
[22] | <cucu>mber  
[41] | <juju>be  
[56] | <papa>ya  
[73] | s<alal> berry
```

Grouping and backreferences

Backreferences and grouping will be very useful for string *replacements*.

OK that was a lot

Learning and testing regexps

Practice with a tester like <https://regexr.com>

Or an app like **Patterns**

The regex engine or “flavor” used by **stringr** is Perl- or PCRE-like.

Regexps in practice

Example: Politics and Placenames

```
library(ukelection2019)
```

Example: Politics and Placenames

```
library(ukelection2019)
```

```
ukvote2019
```

```
