## # ... with 14 more variables: district <chr>, start <chr>, end <chr>,  
## #   religion <chr>, race <chr>, educational_attainment <chr>, job_type1 <chr>,  
## #   job_type2 <chr>, job_type3 <chr>, job_type4 <chr>, job_type5 <lgl>,  
## #   mil1 <chr>, mil2 <chr>, mil3 <chr>
```

We often find ourselves in this situation. We know each file has the same structure, and we would like to use them all at once.

# Loops?

How to read them all in?

One traditional way, which we could do in R, is to write an explicit *loop* that iterated over a vector of filenames, read each file, and then joined the results together in a tall rectangle.

```
# Pseudocode

filenames <- c("01_79_congress.csv", "02_80_congress.csv", "03_81_congress.csv",
              "04_82_congress.csv" [etc etc])

collected_files <- NULL

for(i in 1:length(filenames)) {
  new_file <- read_file(filenames[i])
  collected_files <- append_to(collected_files, new_files)
}
```

# Loops?

You may have noticed we have not written any loops, however.

While loops are still lurking there underneath the surface, what we will do instead is to take advantage of the combination of vectors and functions and *map* one to the other in order to generate results.

Speaking loosely, think of `map()` as a way of iterating without writing loops. You start with a vector of things and you feed it to the function one thing at a time. The function does whatever it does, and you get back output that is the same length as your input.

# Mapping is just iteration for functions

The `purrr` package provides a big family of mapping functions. One reason there are a lot of them is that `purrr`, like the rest of the tidyverse, is picky about data types.

# Mapping is just iteration for functions

The `purrr` package provides a big family of mapping functions. One reason there are a lot of them is that `purrr`, like the rest of the tidyverse, is picky about data types.

So in addition to the basic `map()`, which always returns a *list*, we also have `map_chr()`, `map_int()`, `map_dbl()`, `map_lgl()` and others. They always return the data type indicated by their suffix, or die trying.

# Vectorized arithmetic again

The simplest cases are not that different from the vectorized arithmetic we're already familiar with.

```
a <- c(1:10)
```

```
b <- 1
```

```
# You know what R will do here
```

```
a + b
```

```
## [1]  2  3  4  5  6  7  8  9 10 11
```

# Vectorized arithmetic again

The simplest cases are not that different from the vectorized arithmetic we're already familiar with.

```
a <- c(1:10)
b <- 1
# You know what R will do here
a + b
```

```
## [1]  2  3  4  5  6  7  8  9 10 11
```

R's vectorized rules add `b` to every element of `a`. In a sense, the `+` operation can be thought of as a function that takes each element of `a` and does something with it. In this case "add `b`".

# Vectorized arithmetic again

We can make this explicit by writing a function:

```
add_b <- function(x) {  
  b <- 1  
  x + b # for any x  
}
```

Now:

```
add_b(x = a)
```

```
## [1]  2  3  4  5  6  7  8  9 10 11
```

# Vectorized arithmetic again

Again, R's vectorized approach means it automatically adds `b` to every element of the `x` we give it.

```
add_b(x = 10)
```

```
## [1] 11
```

```
add_b(x = c(1, 99, 1000))
```

```
## [1] 2 100 1001
```

# Iterating in a pipeline

Some operations can't directly be vectorized in this way, which is why we need to manually iterate, or will want to write loops.

```
library(gapminder)
gapminder %>%
  summarize(n_distinct(country),
            n_distinct(continent),
            n_distinct(year),
            n_distinct(lifeExp),
            n_distinct(population))
```

```
## # A tibble: 1 x 5
##   `n_distinct(countr...` `n_distinct(continen...` `n_distinct(year...` `n_distinct(lifeE...
##           <int>           <int>           <int>           <int>
## 1           142             5             12           1626
## # ... with 1 more variable: n_distinct(population) <int>
```

That's tedious to write. Computers are supposed to allow us to avoid that sort of thing.

# Iterating in a pipeline

So how would we iterate this? What we want is to apply the `n_distinct()` function to each column of `gapminder`, but in a way that still allows us to use pipelines and so on.

```
library(gapminder)
gapminder %>%
  summarize(n_distinct(country),
            n_distinct(continent),
            n_distinct(year),
            n_distinct(lifeExp),
            n_distinct(population))
```

```
## # A tibble: 1 x 5
##   `n_distinct(countr...` `n_distinct(continen...` `n_distinct(year...` `n_distinct(lifeE...
##           <int>           <int>           <int>           <int>
## 1           142             5             12           1626
## # ... with 1 more variable: n_distinct(population) <int>
```

Using `n_distinct()` in this context is an idea I got from Rebecca Barter's discussion of `purrr`.

# Iterating in a pipeline

```
map(gapminder, n_distinct)
```

```
## $country  
## [1] 142  
##  
## $continent  
## [1] 5  
##  
## $year  
## [1] 12  
##  
## $lifeExp  
## [1] 1626  
##  
## $pop  
## [1] 1704  
##  
## $gdpPercap  
## [1] 1704
```

Read it as "Feed each column of `gapminder` to the `n_distinct()` function."

# Iterating in a pipeline

Or, in pipeline form:

```
gapminder %>%  
  map(n_distinct)
```

```
## $country  
## [1] 142  
##  
## $continent  
## [1] 5  
##  
## $year  
## [1] 12  
##  
## $lifeExp  
## [1] 1626  
##  
## $pop  
## [1] 1704  
##  
## $gdpPercap  
## [1] 1704
```

You can see we are getting a *list* back

# Iterating in a pipeline

Or, in pipeline form:

```
result <- gapminder %>%  
  map(n_distinct)  
  
class(result)
```

```
## [1] "list"
```

```
result$continent
```

```
## [1] 5
```

```
result[[2]]
```

```
## [1] 5
```

You can see we are getting a *list* back.

# Iterating in a pipeline

In this context, `n_distinct()` is always going to return an integer, though.

```
gapminder %>%  
  map_int(n_distinct)
```

```
## country continent    year  lifeExp      pop gdpPercap  
##      142         5      12    1626    1704      1704
```

The thing about the `map()` family is that they can deal with all kinds of input types and output types.

# Get a vector of filenames

```
filenames <- dir(path = here("data", "congress"),  
  pattern = "*.csv",  
  full.names = TRUE)
```

```
filenames[1:10] # Just displaying the first 10, to save slide space
```

```
## [1] "/Users/kjhealy/Documents/courses/data_wrangling/data/congress/01_79_congress.csv"  
## [2] "/Users/kjhealy/Documents/courses/data_wrangling/data/congress/02_80_congress.csv"  
## [3] "/Users/kjhealy/Documents/courses/data_wrangling/data/congress/03_81_congress.csv"

# Table joins

x		y	
1	x1	1	y1
2	x2	2	y2
3	x3	4	y4

\*Spiffy Join Animatations courtesy [Garrick Aden-Buie](#)

# Left join, **left\_join()**

`left_join(x, y)`

1	x1	1	y1
2	x2	2	y2
3	x3	4	y4

All rows from x, and all columns from x and y. Rows in x with no match in y will have NA values in

# Left join (contd), **left\_join()**

`left_join(x, y)`

1	x1	1	y1
2	x2	2	y2
3	x3	4	y4
		2	y5

If there are multiple matches between x and y, all combinations of the matches are returned.

# Inner join, `inner_join()`

`inner_join(x, y)`

1	x1	1	y1
2	x2	2	y2
3	x3	4	y4

All rows from x where there are matching values in y, and all columns from x and y.

# Full join, **full\_join()**

`full_join(x, y)`

1	x1	1	y1
2	x2	2	y2
3	x3	4	y4

All rows and all columns from both x and y. Where there are not matching values, returns NA for the

# Semi join, **semi\_join()**

`semi_join(x, y)`

1	x1	1	y1
2	x2	2	y2
3	x3	4	y4

All rows from x where there are matching values in y, keeping just columns from x.

# Anti join, **anti\_join()**

`anti_join(x, y)`

1	x1	1	y1
2	x2	2	y2
3	x3	4	y4

All rows from x where there are not matching values in y, keeping just columns from x.

# Left join, **left\_join()**

Most of the time you will be looking to make a **left\_join()**

# Upset plots and a bit of wrangling

## TRACKING SYMPTOMS

On 7 April, around 60% of app users who tested positive for COVID-19 and reported symptoms had lost their sense of smell.

— Anosmia (loss of smell) — Cough — Fatigue  
— Diarrhoea — Shortness of breath — Fever

# Upset plots and a bit of wrangling

```
symptoms <- c("Anosmia", "Cough", "Fatigue",  
              "Diarrhea", "Breath", "Fever")  
names(symptoms) <- symptoms  
symptoms
```

```
##      Anosmia      Cough      Fatigue      Diarrhea      Breath      Fever  
## "Anosmia"    "Cough"    "Fatigue" "Diarrhea"    "Breath"    "Fever"
```

# Upset plots and a bit of wrangling

```
# An Excel file!
dat <- readxl::read_xlsx(here("data", "symptoms.xlsx"))
dat %>% print(n = nrow(dat))
```

```
## # A tibble: 32 x 2
##   combination      count
##   <chr>          <dbl>
## 1 Anosmia             140
## 2 Cough                57
## 3 Fatigue            198
## 4 Diarrhea            12
## 5 Breath               5
## 6 Fever               11
## 7 Cough&Fatigue       179
## 8 Fatigue&Fever        28
## 9 Breath&Fatigue       10
## 10 Diarrhea&Fatigue     43
## 11 Anosmia&Fatigue     281
## 12 Breath&Cough         1
## 13 Anosmia&Diarrhea&Fatigue 64
## 14 Breath&Cough&Fatigue 22
## 15 Anosmia&Cough&Fatigue 259
## 16 Anosmia&Fever&Fatigue 46
## 17 Cough&Fever&Fatigue  54
## 18 Cough&Diarrhea       7
## 19 Cough&Diarrhea&Fatigue 31
## 20 Anosmia&Breath&Cough&Fatigue 26
## 21 Anosmia&Cough&Fatigue&Fever 69
## 22 Anosmia&Breath&Cough&Diarrhea&Fatigue 18
## 23 Anosmia&Breath&Cough&Fatigue&Fever 17
## 24 Breath&Cough&Fatigue&Fever 11
## 25 Breath&Cough&Diarrhea&Fatigue 7
```

# Upset plots and a bit of wrangling

```
subsets <- dat %>%  
  pull(combination)  
  
## Check if each subset mentions each symptom or not  
symptom_mat <- map_dfc(subsets, str_detect, symptoms) %>%  
  data.frame() %>%  
  t() %>% # transpose the result, this is a little gross, sorry  
  as_tibble(.name_repair = "unique")  
  
colnames(symptom_mat) <- symptoms  
symptom_mat$count <- dat$count
```

# Upset plots and a bit of wrangling

Now we have a table we can do something with.

```
symptom_mat %>% print(n = nrow(symptom_mat))
```

```
