Manipulating tables with dplyr

Data Wrangling, Session 3

Kieran Healy

Code Horizons

July 19, 2024

dplyr is your toolkit for tabular data

Time to play with some data

Load our libraries

```
library(here) # manage file paths
library(socviz) # data and some useful functions
library(tidyverse) # your friend and mine
```

Tidyverse components, again

```
library(tidyverse)Call the package and ...Loading tidyverse: ggplot2□ Draw graphsLoading tidyverse: tibble□ Nicer data tablesLoading tidyverse: tidyr□ Tidy your dataLoading tidyverse: readr□ Get data into RLoading tidyverse: purrr□ Fancy IterationLoading tidyverse: dplyr□ Action verbs for tables
```

Other tidyverse components

forcats

haven

lubridate

readxl

stringr

reprex

☐ Deal with factors

Dates, Durations, Times

✓ Import from spreadsheets

◁ Strings and Regular Expressions

✓ Make reproducible examples

Not all of these are attached when we do library (tidyverse)

dplyr lets you work with tibbles

Remember, tibbles are tables of data where the columns can be of different types, such as numeric, logical, character, factor, etc.

We'll use dplyr to transform and summarize our data.

We'll use the pipe operator, ▶, to chain together sequences of actions on our tables.

dplyr's core verbs

dplyr draws on the logic and language of database queries

Some actions to take on a single table

Group the data at the level we want, such as "Religion by Region" or "Children by School".

Subset either the rows or columns of or table—i.e. remove them before doing anything.

Mutate the data. That is, change something at the *current* level of grouping. Mutating adds new columns to the table, or changes the content of an existing column. It never changes the number of rows.

Summarize or aggregate the data. That is, make something new at a *higher* level of grouping. E.g., calculate means or counts by some grouping variable. This will generally result in a smaller, *summary* table. Usually this will have the same number of *rows* as there are *groups* being summarized.

For each action there's a function

Group using group_by().

Subset has one action for rows and one for columns. We filter() rows and select() columns.

Mutate tables (i.e. add new columns, or re-make existing ones) using mutate().

Summarize tables (i.e. perform aggregating calculations) using summarize().

Group and Summarize

General Social Survey data: gss_sm

```
## library(socviz) # if not loaded
 gss_sm
# A tibble: 2,867 × 32

```

Notice how the tibble already tells us a lot.

Summarizing a Table

Here's what we're going to do:

1. Individual-Level GSS Data on Region and Religion

id	bigregion	religion
1014	Midwest	Protestant
1544	South	Protestant
665	Northeast	None
1618	South	None
2115	West	Catholic
417	South	Protestant
2045	West	Protestant
1863	Northeast	Other
1884	Midwest	Christian
1628	South	Protestant

2. Summary Count of Religious Preferences by Census Region

bigregio	n religion	N
Northeast	Protestant	123
Northeast	Catholic	149
Northeast	Jewish	15
Northeast	None	97
Northeast	Christian	14
Northeast	Other	31

3. Percent Religious Preferences by Census Region

bigregion	religion	N	pct
Northeast	Protestant	123	28.3
Northeast	Catholic	149	34.3
Northeast	Jewish	15	3.4
Northeast	None	97	22.3
Northeast	Christian	14	3.2
Northeast	Other	31	7.1

Summarizing a Table

```
gss_sm >
  select(id, bigregion, religion)
# A tibble: 2,867 × 3
     id bigregion religion
  <dbl> <fct>
                 <fct>
     1 Northeast None
   2 Northeast None
   3 Northeast Catholic
   4 Northeast Catholic
   5 Northeast None
   6 Northeast None
7 7 Northeast None
8 8 Northeast Catholic
9 9 Northeast Protestant
   10 Northeast None
# i 2,857 more rows
```

We're just taking a look at the relevant columns here.

Group by one column or variable

```
gss_sm ▷
  group_by(bigregion)
# A tibble: 2,867 × 32
# Groups:
           bigregion [4]
           id ballot
                            age childs sibs
                                              degree race sex region income16

# i 14 more rows
```

We're going to be doing this **group_by()** ... **n()** step a lot. Some shorthand for it would be useful.

Three options for counting up rows

Use n()

```
gss_sm ▷
  group_by(bigregion, religion) ▷
  summarize(n = n())
```

```
# A tibble: 24 \times 3
# Groups: bigregion [4]
   bigregion religion
   <fct>
            <fct>
                       <int>
1 Northeast Protestant 158
 2 Northeast Catholic
                         162
3 Northeast Jewish
                          27
4 Northeast None
                         112
5 Northeast Other
6 Northeast <NA>
7 Midwest Protestant
                         325
8 Midwest Catholic
                         172
 9 Midwest Jewish
                          3
10 Midwest None
                         157
# i 14 more rows
```

Use tally()

```
gss_sm ▷
group_by(bigregion, religion) ▷
tally()
```

```
# A tibble: 24 × 3
# Groups: bigregion [4]
  bigregion religion

One step; result is not grouped.

Pass results on to ... a table

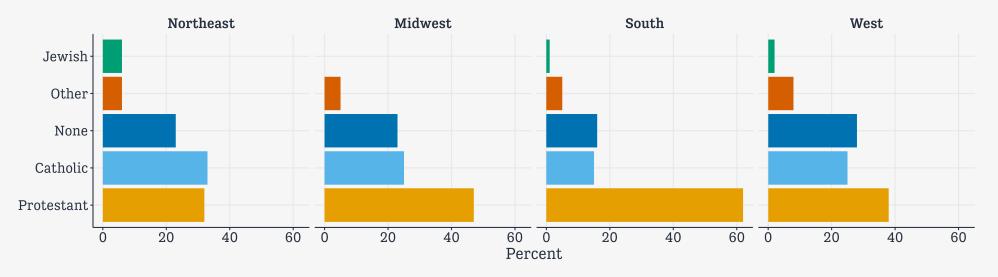

```
gss_sm >
  count(bigregion, religion) >
  pivot_wider(names_from = bigregion, values_from = n) >
  knitr::kable()
```

religion	Northeast	Midwest	South	West
Protestant	158	325	650	238
Catholic	162	172	160	155
Jewish	27	3	11	10
None	112	157	170	180
Other	28	33	50	48
NA	1	5	11	1

More on pivot_wider() and kable() soon...

Pass results on to ... a graph

```
gss_sm >
  group_by(bigregion, religion) >
  tally() >
  mutate(pct = round((n/sum(n))*100), 1) >
  drop_na() >
  ggplot(mapping = aes(x = pct, y = reorder(religion, -pct), fill = religion)) +
  geom_col() +
  labs(x = "Percent", y = NULL) +
  guides(fill = "none") +
  facet_wrap(~ bigregion, nrow = 1)
```

Pass results on to ... an object

You can do it like this ...

```
rel_by_region ← gss_sm ▷
  count(bigregion, religion) ▷
  mutate(pct = round((n/sum(n))*100, 1))
rel_by_region

Right assignmment is a thing, like Left

Left assignment is standard

```
gss_tab ← gss_sm ▷
count(bigregion, religion)
```

This may feel awkward with a pipe: "gss_tab *gets* the output of the following pipeline."

Right assignment also works!

```
gss_sm ⊳
count(bigregion, religion) → gss_tab
```

Without any authority, I assert that right-assignment should be read as, e.g., "This pipeline *begets* gss_tab"

Check by summarizing

```
rel_by_region ← gss_sm ▷
  count(bigregion, religion) ▷
  mutate(pct = round((n/sum(n))*100, 1))
rel_by_region
# A tibble: 24 × 4
  bigregion religion
                           pct
  <fct> <fct>

# i 14 more rows
```

```
## Each region should sum to ~100
rel_by_region >
    group_by(bigregion) >
    summarize(total = sum(pct))

# A tibble: 4 × 2
    bigregion total
    <fct> <dbl>
1 Northeast 17
2 Midwest 24.3
3 South 36.7
4 West 22
```

No! What has gone wrong here?

Hm, did I sum over right group?

Check by summarizing

```
rel_by_region ← gss_sm ▷
  count(bigregion, religion) ▷
  mutate(pct = round((n/sum(n))*100, 1))
```

count() returns ungrouped results, so there are no
groups carry forward to the mutate() step.

```
rel_by_region >
   summarize(total = sum(pct))

# A tibble: 1 × 1
   total
   <dbl>
1  100
```

With **count()**, the pct values here are the marginals for the whole table.

Check by summarizing

```
rel_by_region ← gss_sm ▷
  count(bigregion, religion) ▷
  mutate(pct = round((n/sum(n))*100, 1))
```

count() returns ungrouped results, so there are no
groups carry forward to the mutate() step.

```
rel_by_region >
   summarize(total = sum(pct))

# A tibble: 1 × 1
   total
   <dbl>
1 100
```

With **count()**, the pct values here are the marginals for the whole table.

```
rel_by_region ← gss_sm ▷
  group_by(bigregion, religion) ▷
  tally() >
  mutate(pct = round((n/sum(n))*100, 1))
# Check
rel_by_region ▷
  group_by(bigregion) ▷
  summarize(total = sum(pct))
# A tibble: 4 \times 2
  bigregion total
  <fct>
            <dbl>
1 Northeast 100
2 Midwest
            99.9
           100
3 South
4 West
            100.
```

We get some rounding error because we used round () after summing originally.

Two lessons

Check your tables!

Pipelines feed their content forward, so you need to make sure your results are not incorrect.

Often, complex tables and graphs can be disturbingly plausible even when wrong.

So, figure out what the result should be and test it!

Starting with simple or toy cases can help with this process.

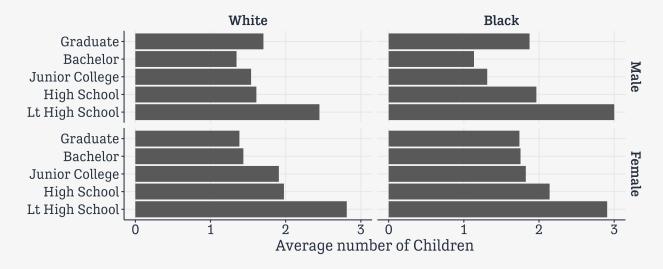

Two lessons

Inspect your pipes!

Understand pipelines by running them forward or peeling them back a step at a time.

This is a *very* effective way to understand your own and other people's code.

Another example

gss_sm

```

```

Use where () to test columns.

When telling where() to use is.integer() to test each column, we don't put parentheses at the end of its name. If we did, R would try to evaluate is.integer() right then, and fail:

```
> organdata ▷
+ select(country, year, where(is.integer()))
Error: ② arguments passed to 'is.integer' which requires 1
Run `rlang::last_error()` to see where the error occurred.
```

This is true in similar situations elsewhere as well.

```

```

We have functions like e.g. is.character(), is.numeric(), is.logical(), is.factor(), etc. All return either TRUE or FALSE.

Sometimes we don't pass a function, but do want to use the result of one:

```
organdata ⊳
  select(country, year, starts_with("gdp"))
# A tibble: 238 × 4
  country year
                      gdp gdp_lag

```

Also a bit awkward. There's no built-in "Not in" operator.

A custom operator

```
`%nin%` \leftarrow Negate(`%in%`) # this operator is included in the socviz package
organdata ▷
  filter(country %nin% my countries)
# A tibble: 182 × 21
   country year

```

The backticks are special here because we need to name an operator.

Using across()

Do more than one thing

Earlier we saw this:

```
gss_sm >
  group_by(race, sex, degree) ▷
  summarize(n = n(),
           mean_age = mean(age, na.rm = TRUE),
           mean_kids = mean(childs, na.rm = TRUE))
# A tibble: 34 \times 6
# Groups: race, sex [6]
  race sex
              degree
                                n mean_age mean_kids
  <fct> <fct> <fct>
                                     <dbl>
                                               <dbl>
                             <int>

Do more than one thing

Similarly for organdata we might want to do:

```
organdata ⊳
  group_by(consent_law, country) ▷
  summarize(donors_mean = mean(donors, na.rm = TRUE),
             donors_sd = sd(donors, na.rm = TRUE),
             gdp_mean = mean(gdp, na.rm = TRUE),
             health mean = mean(health, na.rm = TRUE),
             roads mean = mean(roads, na.rm = TRUE))
# A tibble: 17 × 7
            consent_law [2]
# Groups:
   consent_law country
                            donors mean donors sd gdp mean health mean roads mean
   <chr>
               <chr>
                                  <dbl>
                                             <dbl>
                                                      <dbl>
                                                                   <dbl>
                                                                              <dbl>

```

my_vars are selected by across()

We use all_of() or any_of() to be explicit

list() of the form result = function gives the new columns that
will be calculated.na.rm = TRUE is passed through to the functions
inside the list()

We can calculate more than one thing

```
my_vars ← c("gdp", "donors", "roads")
organdata ⊳
  group_by(consent_law, country) >
  summarize(across(my_vars,
                   list(avg = mean,
                        sd = var,
                        md = median),#<<
                   na.rm = TRUE)
# A tibble: 17 × 11

Name new columns with . names

In tidyverse functions, arguments that begin with a "." generally have it in order to avoid confusion with existing items, or are "pronouns" referring to e.g. "the name of the thing we're currently talking about as we evaluate this function".

This all works with mutate (), too

```
organdata ⊳
  mutate(across(where(is.character), toupper)) ▷
  select(where(is.character))
# A tibble: 238 × 7

You can see that **slice_max()** respects grouping.

There's slice_min(), slice_head(), slice_tail(), slice_sample(), and the most general one, slice().
