#### Tidyverse components, again

#### library(tidyverse)

```
Loading tidyverse: ggplot2
Loading tidyverse: tibble
Loading tidyverse: tidyr
Loading tidyverse: readr
Loading tidyverse: purrr
Loading tidyverse: dplyr
```

#### Tidyverse components, again

#### library(tidyverse)

```
Loading tidyverse: ggplot2
Loading tidyverse: tibble
Loading tidyverse: tidyr
Loading tidyverse: readr
Loading tidyverse: purrr
Loading tidyverse: dplyr
```

- **■** Draw graphs
- Nicer data tables
- **◄** Tidy your data
- Get data into R
- **◄** Cool functional programming stuff
- **◄** Action verbs for manipulating data

#### Other tidyverse components

```
forcats
haven
lubridate
readxl
reprex
stringr
```

#### Other tidyverse components

forcats
haven
lubridate
readxl
reprex
stringr

- Deal with Factors
- **⋖** Get Stata, SPSS, etc
- Work with date formats
- **◄** Read spreadsheets
- **◄** Create reproducible examples
- **◄** Regular Expression tools for strings

Not all of these are attached when we do library(tidyverse)

Remember, tibbles are tables of data where the columns can be of different types, such as numeric, logical, character, factor, etc.

Remember, tibbles are tables of data where the columns can be of different types, such as numeric, logical, character, factor, etc.

We'll use dplyr to transform and summarize our data.

Remember, tibbles are tables of data where the columns can be of different types, such as numeric, logical, character, factor, etc.

We'll use dplyr to transform and summarize our data.

We'll use the pipe operator, **%>%**, to chain together sequences of actions on our tables.

Remember, tibbles are tables of data where the columns can be of different types, such as numeric, logical, character, factor, etc.

We'll use dplyr to transform and summarize our data.

We'll use the pipe operator, **%>%**, to chain together sequences of actions on our tables.

# dplyr draws on the logic and language of database queries, where the focus is on manipulating tables

**Group** the data at the level we want, such as "Religion by Region" or "Children by School by District", so as to present data at that level.

**Group** the data at the level we want, such as "Religion by Region" or "Children by School by District", so as to present data at that level.

**Subset** either the rows or columns of or table.

**Group** the data at the level we want, such as "Religion by Region" or "Children by School by District", so as to present data at that level.

**Subset** either the rows or columns of or table.

**Mutate** the data. That is, change something at the *current* level of grouping. Mutating adds new columns to the table, or changes the content of an existing column. This won't change the number of rows.

**Group** the data at the level we want, such as "Religion by Region" or "Children by School by District", so as to present data at that level.

**Subset** either the rows or columns of or table.

**Mutate** the data. That is, change something at the *current* level of grouping. Mutating adds new columns to the table, or changes the content of an existing column. This won't change the number of rows.

**Summarize** or aggregate the data. That is, make something new at a *higher* level of grouping. E.g., calculate means or counts by some grouping variable. This will generally result in a smaller, *summary* table.

**Group** using group\_by().

**Group** using group\_by().

**Subset** has one action for rows and one for columns. We filter() rows and select() columns.

**Group** using group\_by().

**Subset** has one action for rows and one for columns. We filter() rows and select() columns.

**Mutate** tables (i.e. add new columns, or re-make existing ones) using mutate().

**Group** using group\_by().

**Subset** has one action for rows and one for columns. We filter() rows and select() columns.

**Mutate** tables (i.e. add new columns, or re-make existing ones) using mutate().

**Summarize** tables (i.e. perform aggregating calculations) using summarize().

```

Notice how the tibble already tells us a lot.

#### Summarizing a Table

Here's what we're going to do:

## 1. Individual-Level GSS Data on Region and Religion

id	bigregion	religion
1014	Midwest	Protestant
1544	South	Protestant
665	Northeast	None
1618	South	None
2115	West	Catholic
417	South	Protestant
2045	West	Protestant
1863	Northeast	Other
1884	Midwest	Christian
1628	South	Protestant

### 2. Summary Count of Religious Preferences by Census Region

bigregion	n religion	N
Northeast	Protestant	123
Northeast	Catholic	149
Northeast	Jewish	15
Northeast	None	97
Northeast	Christian	14
Northeast	Other	31

### 3. Percent Religious Preferences by Census Region

bigregion	religion	N	pct
Northeast	Protestant	123	28.3
Northeast	Catholic	149	34.3
Northeast	Jewish	15	3.4
Northeast	None	97	22.3
Northeast	Christian	14	3.2
Northeast	Other	31	7.1

#### Summarizing a table

```
## Just take a look at the columns we will work on
gss_sm %>%
  select(id, bigregion, religion)
## # A tibble: 2,867 x 3
##
        id bigregion religion
     <dbl> <fct> <fct>
## 1
        1 Northeast None
## 2 2 Northeast None
## 3 3 Northeast Catholic
     4 Northeast Catholic
## 4
## 5
        5 Northeast None
## 6 6 Northeast None
#非 7 7 Northeast None
## 8
     8 Northeast Catholic
     9 Northeast Protestant
## 9
## 10
        10 Northeast None
## # ... with 2,857 more rows
```

We're just taking a look at the relevant columns here.

#### Group by *one* column or variable

```
gss sm %>%
   group_by(bigregion)
## # A tibble: 2,867 x 32
## # Groups: bigregion [4]
##
      vear

mutate() is very clever. See how we can immediately use freq, even though we are creating it in the same mutate() expression.

#### **Convenience functions**

```
gss_sm %>%
  group by(bigregion, religion) %>%
  summarize(total = n()) %>%
  mutate(freq = total / sum(total),
          pct = round((freq*100), 1))
## # A tibble: 24 x 5
  # Groups: bigregion [4]
     bigregion religion total
                                 freq
                                        pct
     <fct>
               <fct>
                         <int>
                                <dbl> <dbl>

We're going to be doing this group\_by() ... n() step a lot. Some shorthand for it would be useful.

# Three options for counting up rows

#### Do it yourself

```
gss_sm %>%
  group_by(bigregion, religion) %>%
  summarize(n = n())
## # A tibble: 24 x 3
## # Groups: bigregion [4]
     bigregion religion
                              n
     <fct>

## # ... with 14 more rows
```

```
Hm, did I sum over right group?
```

No! What has gone wrong here?

```
rel_by_region <- gss_sm %>%
   count(bigregion, religion) %>%
   mutate(pct = round((n/sum(n))*100, 1))
```

count() returns ungrouped results, so no
groups carry forward to the mutate() step.

```
rel_by_region %>%
   summarize(total = sum(pct))

### # A tibble: 1 x 1
### total
### <dbl>
### 1 100
```

With count(), the pct values here are the marginals for the whole table.

```
rel_by_region <- gss_sm %>%
   count(bigregion, religion) %>%
   mutate(pct = round((n/sum(n))*100, 1))
```

count() returns ungrouped results, so no
groups carry forward to the mutate() step.

```
rel_by_region %>%
   summarize(total = sum(pct))

### # A tibble: 1 x 1
### total
### <dbl>
### 1 100
```

With count(), the pct values here are the marginals for the whole table.

```
rel_by_region <- gss_sm %>%
  group_by(bigregion, religion) %>%
  tally() %>%
  mutate(pct = round((n/sum(n))*100, 1))
# Check
rel by region %>%
   group by(bigregion) %>%
  summarize(total = sum(pct))
## # A tibble: 4 x 2
## bigregion total
   <fct>
              <dbl>
## 1 Northeast 100
## 2 Midwest
             99.9
## 3 South
              100
## 4 West
              100.
```

We get some rounding error because we used round() after summing originally.

#### Check your tables!

Pipelines feed their content forward, so you need to make sure your results are not incorrect.

#### Check your tables!

Pipelines feed their content forward, so you need to make sure your results are not incorrect.

Often, complex tables and graphs can be disturbingly plausible even when wrong.

#### Check your tables!

Pipelines feed their content forward, so you need to make sure your results are not incorrect.

Often, complex tables and graphs can be disturbingly plausible even when wrong.

So, figure out what the result should be and test it!

#### Check your tables!

Pipelines feed their content forward, so you need to make sure your results are not incorrect.

Often, complex tables and graphs can be disturbingly plausible even when wrong.

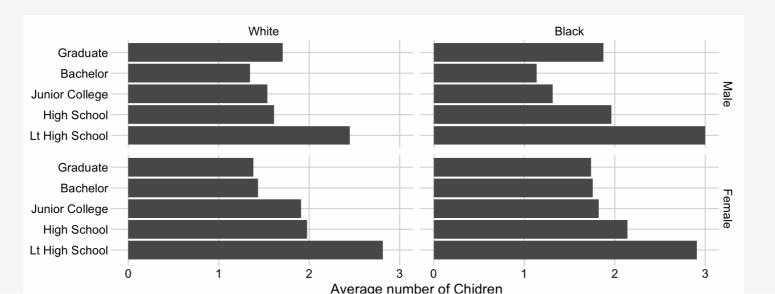

So, figure out what the result should be and test it!

Starting with simple or toy cases can help with this process.

#### Inspect your pipes!

Understand pipelines by running them forward or peeling them back a step at a time.

This is a *very* effective way to understand your own and other people's code.

```

Use where () to test columns.

organdata %>%

When telling where() use is.integer() to test each column, we don't put parentheses at the end of its name. If we did, R would try to evaluate is.integer() right then, and fail:

```
> organdata %>%
+ select(country, year, where(is.integer()))
Error: 0 arguments passed to 'is.integer' which requires 1
Run `rlang::last_error()` to see where the error occurred.
```

This is true in similar situations elsewhere as well.

```
organdata %>%
   select(country, year, where(is.character))

## # ... with 228 more rows
```

We have functions like e.g. is.character(), is.numeric(), is.logical(), is.factor(), etc. All return either TRUE or FALSE.

Sometimes we don't pass a function, but do want to use the result of one:

```
organdata %>%
   select(country, year, starts with("gdp"))
## # A tibble: 238 x 4
      country
               year
                          gdp gdp_lag

```

Also a bit awkward. There's no built-in "Not in" operator.

## Negating %in%

#### We can make one!

```
`%nin%` <- Negate(`%in%`) # this operator is included in the socviz package
```

(The backticks are special here because we need to name an operator.)

## Negating %in%

#### We can make one!

organdata %>%

```

This works, but it's really tedious. Also error-prone.

### Doing more than one thing with across()

Instead, use across() to apply a function to more than one column.

```
my vars <- c("gdp", "donors", "roads")</pre>
## nested parens again, but it's worth it
organdata %>%
  group by(consent law, country) %>%
  summarize(across(my vars,
                    list(avg = mean),
                    na.rm = TRUE)
## # A tibble: 17 x 5
## # Groups:
             consent law [2]
      consent_law country
                                 gdp avg donors avg roads avg

```

my\_vars are selected by across()

list() of the form result = function gives the new columns that will be calculated.

na.rm = TRUE is passed through to the functions inside the list()

# We can calculate more than one thing

```
my vars <- c("gdp", "donors", "roads")</pre>
organdata %>%
  group by(consent law, country) %>%
  summarize(across(my vars,
                   list(avg = mean,
                        sd = var.
                        md = median).
                   na.rm = TRUE)

#### Name new columns with . names

In tidyverse functions, arguments that begin with a "." generally have it in order to avoid confusion with existing items, or are "pronouns" referring to e.g. "the name of the thing we're currently talking about as we evaluate this function".

```
## # A tibble: 17 x 41

                                 19.8
## # ... with 12 more rows
```

Using arrange() to order rows in this way won't respect groupings.

### More generally ...

```
organdata %>%
  group_by(consent_law, country) %>%
  summarize(donors = mean(donors, na.rm = TRUE)) %>%
  slice max(donors, n = 5)
## # A tibble: 10 x 3
## # Groups: consent_law [2]
###
     consent law country
                                donors
###
     <chr>
                 <chr>
                                 <dbl>
                                  20.0
   1 Informed
               United States
   2 Informed
                Ireland
                                  19.8
   3 Informed
                 Canada
                                  14.0
   4 Informed
                 Netherlands
                                  13.7
```

You can see that slice\_max() respects grouping.

                                                         38407 Deaths
## 10 2021-02-26 NY
                             NA
                                                 death
                                                         38321 Deaths
## # ... with 361 more rows
```

Here the count measure is *cumulative* deaths. What if we want to recover the daily count for all the states in the data?

### An application

dplyr has lead() and lag() functions. These allow you to access the previous and next values in a vector. You can calculate offsets this way.

# An application

#### We can write the expression directly:

9 2021-02-27 NY

## # ... with 361 more rows

## 10 2021-02-26 NY

```
covus %>%
  select(-data quality grade) %>%
  filter(measure == "death") %>%
  group by(state) %>%
  arrange(date) %>%
  mutate(deaths daily = count - lag(count, order by = date)) %>%
  arrange(state, desc(date)) %>%
  filter(state %in% "NY")
## # A tibble: 371 x 7
## # Groups: state [1]
                 state fips measure count measure label deaths daily
     date
     <date>
                 <chr> <chr> <chr>
                                     <dbl> <chr>
                                                                <dbl>
   1 2021-03-07 NY
                                     39029 Deaths
                             death
                                                                   59

#### Writing our own functions

But we could also write a function to do this.

We write functions using the special function() function.\*

```
my_fun <- function(x) {
    x + 1
}
my_fun # we've created the function; it's just an object
## function(x) {
    ##    x + 1
    ## }

my_fun(x = 1) # But we can supply it with an input!
## [1] 2

my_fun(10)
## [1] 11</pre>
```

<sup>\*</sup>Nerds love this sort of stuff.

#### Writing our own functions

We write our function. It's just the expression we originally wrote, wrapped up.

```
get_daily_count <- function(count, date){
  count - lag(count, order_by = date)
}</pre>
```

This function has no generality, error-handling, or anything else. It's a once-off.

#### Writing our own functions

#### Tidy moving averages with slider

dplyr's window functions don't include moving averages.

There are several options, notably RcppRoll

We'll use the slider package.

```
# install.packages("slider")
library(slider)
```

## Tidy moving averages with slider

```
covus %>%
  filter(measure == "death") %>%
  select(-data quality grade) %>%
  group by(state) %>%
  arrange(date) %>%
  mutate(
    deaths daily = get daily count(count, date),
    deaths7 = slide mean(deaths daily,
                         before = 7.
                         na rm = TRUE)) \%>\%
  arrange(state, desc(date)) %>%
  filter(state %in% "NY")
## # A tibble: 371 x 8
## # Groups: state [1]
                state fips measure count measure label deaths daily deaths7
      date
                                     <dbl> <chr>
                                                                        <dbl>

## Tidy moving averages with slider

```
deaths7 = slide_mean(deaths_daily, #<<
before = 7, #<<
na_rm = TRUE)) %>% #<<
```

Notice the Tidyverse-style na\_rm argument rather than the usual base na.rm

The package provides a lot of different functions, from general-purpose slide\_max(), slide\_min() to more specialized sliding functions. In particular note e.g. slide\_index\_mean() that addresses some subtleties in averaging over dates with gaps.

#### Tidying up after yourself with relocate()

gss\_sm

                                                                    2 Junior ... White
## 10
         10 2016 Middle A... Northeast
### # ... with 2,857 more rows, and 8 more variables: sex <fct>, padeg <fct>,
       partyid <fct>, polviews <fct>, partners <fct>, partners rc <fct>,
       income16 <fct>, income rc <fct>
```

# Two dplyr gotchas

Let's say you are working with proportions

```
## # A tibble: 4 x 3
## id prop1 prop2
## <chr> <chr> <dbl> <dbl> <dbl> <dbl> ## 1 A 0.1 0.2
## 2 B 0.1 0.21
## 3 C 0.11 0.2
## 4 D 0.1 0.1
```

df

And you want to focus on cases where prop1 *plus* prop2 is greater than 0.3:

And you want to focus on cases where prop1 plus prop2 is greater than 0.3:

## 3 C 0.11 0.2

## 1 A 0.1 0.2 ## 2 B 0.1 0.21

A shouldn't have been included there.

And you want to focus on cases where prop1 plus prop2 is greater than 0.3:

A shouldn't have been included there.

## 1 A 0.1 0.2 ## 2 B 0.1 0.21 ## 3 C 0.11 0.2

This is not dlpyr's fault. It's our floating point friend again.

```
df %>%
  filter(prop1 + prop2 == 0.3)

## # A tibble: 0 x 3
## # ... with 3 variables: id <chr>, prop1 <dbl>, prop2 <dbl>
```

A should have been included here!

This won't give the right behavior either:

```
df %>%
  mutate(prop3 = prop1 + prop2) %>%
  filter(prop3 == 0.3)

## # A tibble: 0 x 4
## # ... with 4 variables: id <chr>, prop1 <dbl>, prop2 <dbl>, prop3 <dbl>
```

#### So, beware.

#### Better:

## 1 A

0.1 0.2

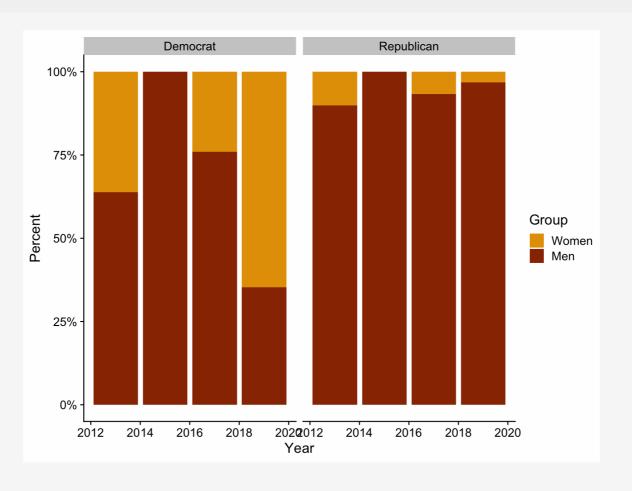

```
df <- read_csv(here("data", "first_terms.csv"))</pre>
df
## # A tibble: 280 x 4
